Chapter 1

Introduction

1.1 Notation

1.2 Block ciphers

Securing communication channels between different parties has been a long-term subject of study for cryptographers and engineers which is essential to our modern world to cope with ever-increasing amounts of devices producing and sharing data. The main way to facilitate high-throughput, confidential communications nowadays is through the use of symmetric cryptography in which two parties share a common secret, called a key, which allows them to encrypt, share and subsequently decrypt messages to achieve confidentiality against third parties. Ciphers can be divided into two categories; block ciphers, which always encrypt fixed-sized messages called blocks, and stream ciphers, which continuously provide encryption for an arbitrarily long, constant stream of data.

A block cipher can be defined as a bijection between the input block (the message) and the output block (the ciphertext). For any block cipher with block size n , we denote the key-dependent encryption and decryption functions as $E_K, D_K : \mathbb{F}_2^n \rightarrow \mathbb{F}_2^n$. The simplest way to characterize this bijection is through a lookup table which yields the highest possible performance as each block can be encrypted by one simple lookup depending on the key and the message. This is not practical though due to most ciphers working with block and key sizes $n, |K| \geq 64$. For a block cipher with $n = 64, |K| = 128$, a space of $2^{64}2^{128}64 = 2^{198}$ is necessary. Considering modern consumer hard

disks being able to store data in the order of 2^{40} , it is easy to see that a lookup table is wholly impractical. We therefore describe block ciphers algorithmically which opens up possibilities for different tradeoffs and security concerns.

1.2.1 GIFT

GIFT[1], first presented in the *CHES 2017* cryptographic hardware and embedded systems conference, is a lightweight block cipher based on a previous design called **PRESENT**, developed in 2007. Its goal is to offer maximum security while being extremely light on resources. Modern battery-powered devices like RFID tags or low-latency operations like on-the-fly disc encryption present strong hardware and power constraints. **GIFT** aims to be a simple, low-energy cipher suited for these kinds of applications.

GIFT comes in two variants; **GIFT-64** working with 64-bit blocks and **GIFT-128** working with 128-bit blocks. In both cases, the key is 128 bits long. The design is a very simple, round-based substitution-permutation network (SPN). One round consists in a sequential application of the confusion layer by means of 4-bit S-boxes and subsequent diffusion through bit permutation. After the bit permutation, a round key is added to the cipher state and the single round is complete. **GIFT-64** uses 28 rounds while **GIFT-128** uses 40 rounds.

Figure 1.1: Two rounds of GIFT-64

Substitution layer

The input of **GIFT** is split into 4-bit nibbles which are then fed into 16 S-boxes for **GIFT-64** and 32 S-boxes for **GIFT-128**. The S-box $S : \mathbb{F}_2^4 \rightarrow \mathbb{F}_2^4$ is defined as follows:

x	0	1	2	3	4	5	6	7	8	9	a	b	c	d	e	f
$S(x)$	1	a	4	c	6	f	3	9	2	d	b	7	5	0	8	e

Permutation layer

The permutation P works on individual bits and maps bit b_i to $b_{P(i)}$, $i \in \{0, 1, \dots, n-1\}$. The different permutations for **GIFT-64** and **GIFT-128** can be expressed by:

$$P_{64}(i) = 4 \left\lfloor \frac{i}{16} \right\rfloor + 16 \left(\left(3 \left\lfloor \frac{i \bmod 16}{4} \right\rfloor + (i \bmod 4) \right) \bmod 4 \right) + (i \bmod 4)$$

$$P_{128}(i) = 4 \left\lfloor \frac{i}{16} \right\rfloor + 32 \left(\left(3 \left\lfloor \frac{i \bmod 16}{4} \right\rfloor + (i \bmod 4) \right) \bmod 4 \right) + (i \bmod 4)$$

Round key addition

The last step of each round consists in XORing a round key R_i to the cipher state. The new cipher state s_{i+1} after each full round is therefore given by

$$s_{i+1} = P(S(s_i)) \oplus R_i$$

Round key extraction and key schedule

Round key extraction differs for **GIFT-64** and **GIFT-128**. Let $K = k7||k6||\dots||k0$ denote the 128-bit key state.

GIFT-64 . We extract two 16-bit words $U||V = k_1||k_0$ from the key state. u_i and v_i are XORed to r_{4i+1} and r_{4i} of the round key R respectively.

GIFT-128 . We extract two 32-bit words $U||V = k_5||k_4||k_1||k_0$ from the key state. u_i and v_i are XORed to r_{4i+2} and b_{4i+1} of the round key R respectively.

In both cases, we additionally XOR a round constant $C = c_5c_4c_3c_2c_1c_0$ to bit positions $n - 1, 23, 19, 15, 11, 7, 3$. The round constants are generated using a 6-bit affine linear-feedback shift register and have the following values:

Rounds	Constants
1 - 16	01,03,07,0F,1F,3E,3D,3B,37,2F,1E,3C,39,33,27,0E
17 - 32	1D,3A,35,2B,16,2C,18,30,21,02,05,0B,17,2E,1C,38
33 - 48	31,23,06,0D,1B,36,2D,1A,34,29,12,24,08,11,22,04

The key state is then updated by setting $k_1 \leftarrow k_1 \ggg 2$, $k_0 \leftarrow k_0 \ggg 12$ and rotating the new state 32 bits to the right:

$$k_7||k_6||\dots||k_1||k_0 \leftarrow k_1 \ggg 2||k_0 \ggg 12||k_7||k_6||\dots||k_3||k_2$$

Chapter 2

Implementation strategies

Due to the structural differences of SPN- and Feistel network-based ciphers, we shall analyze these two separately.

2.1 Strategies for SPN

Three implementation strategies for substitution-permutation networks are introduced by [2]:

- Table-based implementations
- `vperm` implementations
- Bitslice implementations

2.1.1 Table-based

Table-driven programming is a simple way to increase performance of operations by tabulating the results, therefore requiring only a single memory access to acquire the result. This approach is obviously limited to manageable table sizes, so while tabulating a function like the AES S-box $S_{AES} : \mathbb{F}_2^8 \rightarrow \mathbb{F}_2^8$ requires only 2^{11} space, tabulating the **GIFT** permutation layer $P_{GIFT} : \mathbb{F}_2^{64} \rightarrow \mathbb{F}_2^{64}$ would require 2^{70} space, which is totally unfeasible.

A common approach is to tabulate the output of each S-box, including the diffusion layer, and then XORing the results together. Let n denote the internal cipher state size and s the size of a single S-box in bits. For

each S-box $S_i, i \in \{0, \dots, \frac{n}{s}\}$, we can construct a mapping $T_i : \mathbb{F}_2^s \rightarrow \mathbb{F}_2^n$ representing substitution with subsequent permutation of that single S-box. The cipher state before round key addition is then given by $\bigoplus_{i=0}^{\frac{n}{s}-1} T_i(m_i)$ for each s -bit message chunk m_i . This approach requires space of $\frac{n}{s} |\mathbb{F}_2^s| n = \frac{n^2 2^s}{s}$ bits, which, for **GIFT-64**, results in a manageable size of $\frac{64^2 2^4}{4} = 2^{14}$ bits which equals 16 KiB.

Constructing the tables

For **GIFT-64**, table construction is relatively straightforward and can be done as follows:

Listing 2.1: Table construction algorithm

```

1  tables <- [[]]
2  for sbbox_index from 0 to 15 do
3    for sbbox_input from 0 to 15 do
4      output <- sbbox(sbbox_input)
5      output <- permute(output << (4 * sbbox_index))
6      tables[sbbox_index][sbbox_input] <- output

```

Implementing this algorithm gives us the following table representing the first and second S-box.

x	$T_0(x)$	$T_1(x)$...
0x0	0x1	0x1000000000000	...
0x1	0x8000000020000	0x800000002	...
0x2	0x400000000	0x40000	...
0x3	0x8000400000000	0x800040000	...
0x4	0x400020000	0x40002	...
0x5	0x8000400020001	0x1000800040002	...
0x6	0x20001	0x1000000000002	...
0x7	0x80000000000001	0x1000800000000	...
0x8	0x20000	0x2	...
0x9	0x8000400000001	0x1000800040000	...
0xa	0x8000000020001	0x1000800000002	...
0xb	0x400020001	0x1000000040002	...
0xc	0x400000001	0x1000000040000	...
0xd	0x0	0x0	...
0xe	0x8000000000000	0x800000000	...
0xf	0x8000400020000	0x800040002	...

The tables for **GIFT-128** can be generated in a similar way by looping through all 32 S-boxes instead of 16 on line 3.

2.1.2 Using **vperm**

Nowadays, most instructions set architectures support single-instruction, multiple-data processing. The idea of such an SIMD system is to work on multiple data stored in vectors at once to speed up calculations. For A64, two types of vector processing are available:

1. Advanced SIMD, known as NEON
2. Scalable Vector Extension (SVE)

We will take a look at NEON as this is the type of vector processing supported by the Cortex-A73 processor.

ARM Neon

The register file of the NEON unit is made up of 32 quad-word (128-bit) registers $V[0-31]$, each extending the standard 64-bit floating-point registers $D[0-31]$. These registers are divided into equally sized lanes on which the vector instructions operate. Valid ways to interpret for example the register $V0$ are:

Figure 2.1: Divisions of the V0 register

NEON instructions interpret their operands' layouts (i.e. lane count and width) through the use of suffixes such as **.4S** or **.8H**. For example, adding

eight 16-bit halfwords from register **V1** and **V2** together and storing the result in **V0** can be done as follows:

ADD V0.8H, V1.8H, V2.8H

Figure 2.2: Addition of two vector registers

The plenitude of different processing instructions allow flexible ways to further speed up algorithms having reached their optimizational limit on non-SIMD platforms. **vperm**, a general term standing for *vector permute*, is a common instruction on SIMD machines. Called **TBL** on NEON, it is used for parallel table lookups and arbitrary permutations. It takes two inputs to perform a lanewise lookup:

1. A register with lookup values
2. Two or more registers containing data

S-box lookup

This instruction can be used to implement S-box lookup of all 16 S-boxes in a single instruction. We do this by packing our 64-bit cipher state $s = s_{15}||s_{14}||\dots||s_0$ into a vector register V_0 . Because we can only operate on whole bytes, we put each 4-bit S-box into an 8-bit lane which neatly fits into the 128-bit registers. We then put the S-box itself into register V_1 which will be used as the data register for the table lookup.

The confusion layer can now be performed through one **TBL** instruction:

TBL V0.16B, V1.16B, V0.16B

Figure 2.3: Performing the S-Box lookup in parallel

2.1.3 Bitslicing

Bitslicing refers to the technique of splitting up n bits into m slices to achieve a more efficient representation to operate on. The structure of **GIFT** naturally offers possibilities for bitslicing. We split the cipher state bits $b_{63}b_{62} \dots b_0$ into four slices $S_i, i \in \{0, 1, 2, 3\}$ such that the i -th slice contains all i -th bits of the individual S-boxes. This is equivalent to transposing the bit matrix.

$$S = \begin{bmatrix} S_0 \\ S_1 \\ S_2 \\ S_3 \end{bmatrix} = \begin{bmatrix} b_{60}b_{56}b_{52} \dots b_0 \\ b_{61}b_{57}b_{53} \dots b_1 \\ b_{62}b_{58}b_{54} \dots b_2 \\ b_{63}b_{59}b_{55} \dots b_3 \end{bmatrix}$$

Parallel S-Boxes

This representation offers multiple advantages. We first note that computation of the S-box can be executed in parallel, similar to the **vperm** technique above. This can be done by finding an algorithmic way to apply the S-box which has already been proposed by the original **GIFT** authors:

$$\begin{aligned}
S_1 &\leftarrow S_1 \oplus (S_0 \wedge S_2) \\
t &\leftarrow S_0 \oplus (S_1 \wedge S_3) \\
S_2 &\leftarrow S_2 \oplus (t \vee S_1) \\
S_0 &\leftarrow S_3 \oplus S_2 \\
S_1 &\leftarrow S_1 \oplus S_0 \\
S_0 &\leftarrow \neg S_0 \\
S_2 &\leftarrow S_2 \oplus (t \wedge S_1) \\
S_3 &\leftarrow t
\end{aligned}$$

This is very efficient as it only requires six XOR-, three AND and one OR operation.

An important property of the permutation is the fact that bits always stay in their slice. This means we can decompose the permutation P into four permutations $P_i, i \in \{0, 1, 2, 3\}$ and apply these permutations separately to each slice. One possible way to implement a permutation P_i in software is to mask off all bits individually, shift them to their correct position and OR them together:

$$P_i(S_i) = \bigvee_{k=0}^{15} (S_i \wedge m_i) \ll s_i$$

This approach requires 47 operations, meaning all four permutations require over 150 operations which would present a major bottleneck to the round function. We can improve on this by working on multiple message blocks at once and using the aforementioned **vperm** instruction to implement the bit shuffling. We then need only four instructions for the complete diffusion layer.

Using **vperm** for slice permutation

We cannot use the **TBL** instruction directly as we need to shuffle individual bits, but the smallest data we can operate on are bytes. We therefore encrypt $8n$ messages at once which allows us to create bitwise groupings. These messages are put into $4m$ registers with register R_{4i} containing S_0 , register R_{4i+1} containing S_1 and so forth. With block size BS and register size RS , the following must hold:

$$8n \cdot BS = 4m \cdot RS$$

In the case of **GIFT-64** with $BS = 64$ and ARM NEON with $RS = 128$, we get

$$8n \cdot 64 = 4m \cdot 128 \Leftrightarrow n = m$$

$n = m = 1$ would be a valid choice which yields eight messages divided into four registers. We choose $n = m = 2$ so we can directly utilize the algorithm for bit packing presented by the original GIFT authors, although it is simple to adapt this algorithm to only four registers and eight messages by adjusting the **SWAPMOVE** shift and mask values.

Packing the data into bitslice format

Let a, b, \dots, p be sixteen messages of length 64 with subscripts denoting individual bits. We first put these messages into eight SIMD registers V_0, V_1, \dots, V_7 :

$$\begin{aligned} V_0 &= b||a & V_4 &= j||i \\ V_1 &= d||c & V_5 &= l||k \\ V_2 &= f||e & V_6 &= n||m \\ V_3 &= h||g & V_7 &= p||o \end{aligned}$$

We then use the **SWAPMOVE** technique to bring the data into bitslice format. This operation operates on two registers A, B using mask M and shift value N . It swaps bits in A masked by $(M \ll N)$ with bits in B masked by M in using only three XOR-, one AND- and two shift operations.

$$\begin{aligned} &\text{SWAPMOVE}(A, B, M, N) : \\ &T = ((A \gg N) \oplus B) \wedge M \\ &B = B \oplus T \\ &A = A \oplus (T \ll N) \end{aligned}$$

One caveat of this approach is the fact that NEON registers cannot be shifted in their entirety due to the fact bits are not able to cross lanes. This

leads to the problem of being able to shift at most two lanes of 64 bits at once. We thus need to implement the $\text{shr}(\mathbf{V}, n)$ and $\text{shl}(\mathbf{V}, n)$ operations on our own. This can be done by first extracting the 64-bit lanes a, b out of $V = b||a$, shifting the lanes individually and finally shifting and ORing the crossing bits back into the other lane.

$$\begin{aligned}
&\text{shl}(V, n) : \\
&\quad a, b \quad = V[0], V[1] \\
&\quad c \quad = (a \gg (64 - n)) \\
&\quad a \quad = (a \ll n) \\
&\quad b \quad = (b \ll n) \vee c \\
&\quad V[0], V[1] = a, b
\end{aligned}$$

The following operations group all i th bits of the messages a, c, \dots, o into bytes and puts these into the lower half of the registers $V_{i \bmod 8}$. The same is done for messages b, d, \dots, p , only differing in that the bytes are put into the upper half of the registers.

$\text{SWAPMOVE}(V_0, V_1, 0x5555 \dots 55, 1)$ $\text{SWAPMOVE}(V_4, V_5, 0x5555 \dots 55, 1)$
 $\text{SWAPMOVE}(V_2, V_3, 0x5555 \dots 55, 1)$ $\text{SWAPMOVE}(V_6, V_7, 0x5555 \dots 55, 1)$
 $\text{SWAPMOVE}(V_0, V_2, 0x3333 \dots 33, 2)$ $\text{SWAPMOVE}(V_4, V_6, 0x3333 \dots 33, 2)$
 $\text{SWAPMOVE}(V_1, V_3, 0x3333 \dots 33, 2)$ $\text{SWAPMOVE}(V_5, V_7, 0x3333 \dots 33, 2)$
 $\text{SWAPMOVE}(V_0, V_4, 0x0f0f \dots 0f, 4)$ $\text{SWAPMOVE}(V_1, V_5, 0x0f0f \dots 0f, 4)$
 $\text{SWAPMOVE}(V_2, V_6, 0x0f0f \dots 0f, 4)$ $\text{SWAPMOVE}(V_3, V_7, 0x0f0f \dots 0f, 4)$

With $Ax = o_x m_x k_x j_x g_x e_x c_x a_x$ and $Bx = p_x n_x l_x i_x h_x f_x d_x b_x$ denoting byte groups, our data now has the following permutation-friendly format:

n	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
V_0	$B56$	$B48$	$B40$	$B32$	$B24$	$B16$	$B8$	$B0$	$A56$	$A48$	$A40$	$A32$	$A24$	$A16$	$A8$	$A0$
V_1	$B57$	$B49$	$B41$	$B33$	$B25$	$B17$	$B9$	$B1$	$A57$	$A49$	$A41$	$A33$	$A25$	$A17$	$A9$	$A1$
V_2	$B58$	$B50$	$B42$	$B34$	$B26$	$B18$	$B10$	$B2$	$A58$	$A50$	$A42$	$A34$	$A26$	$A18$	$A10$	$A2$
V_3	$B59$	$B51$	$B43$	$B35$	$B27$	$B19$	$B11$	$B3$	$A59$	$A51$	$A43$	$A35$	$A27$	$A19$	$A11$	$A3$
V_4	$B60$	$B52$	$B44$	$B36$	$B28$	$B20$	$B12$	$B4$	$A60$	$A52$	$A44$	$A36$	$A28$	$A20$	$A12$	$A4$
V_5	$B61$	$B53$	$B45$	$B37$	$B29$	$B21$	$B13$	$B5$	$A61$	$A53$	$A45$	$A37$	$A29$	$A21$	$A13$	$A5$
V_6	$B62$	$B54$	$B46$	$B38$	$B30$	$B22$	$B14$	$B6$	$A62$	$A54$	$A46$	$A38$	$A30$	$A22$	$A14$	$A6$
V_7	$B63$	$B55$	$B47$	$B39$	$B31$	$B23$	$B15$	$B7$	$A63$	$A55$	$A47$	$A39$	$A31$	$A23$	$A15$	$A7$

Although this would already work, we prefer to have only bits of the same messages in each register - otherwise the permutation would need to operate on two source registers with the added requirement of storing the pre-permutation values for the first four registers, slowing down the round function through superfluous load/stores. This transformation is trivial by use of **TBL** with two data source operands. The final data format we operate on is as follows:

n	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
V_0	A60	A56	A52	A48	A44	A40	A36	A32	A28	A24	A20	A16	A12	A8	A4	A0
V_1	A61	A57	A53	A49	A45	A41	A37	A33	A29	A25	A21	A17	A13	A9	A5	A1
V_2	A62	A58	A54	A50	A46	A42	A38	A34	A30	A26	A22	A18	A14	A10	A6	A2
V_3	A63	A59	A55	A51	A47	A43	A39	A35	A31	A27	A23	A19	A15	A11	A7	A3
V_4	B60	B56	B52	B48	B44	B40	B36	B32	B28	B24	B20	B16	B12	B8	B4	B0
V_5	B61	B57	B53	B49	B45	B41	B37	B33	B29	B25	B21	B17	B13	B9	B5	B1
V_6	B62	B58	B54	B50	B46	B42	B38	B34	B30	B26	B22	B18	B14	B10	B6	B2
V_7	B63	B59	B55	B51	B47	B43	B39	B35	B31	B27	B23	B19	B15	B11	B7	B3

We can now create permutation tables using the specification of the individual slice permutations P_i which are then applied to V_i and V_{i+4} :

j	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
$P_0(j)$	0	12	8	4	1	13	9	5	2	14	10	6	3	15	11	7
$P_1(j)$	4	0	12	8	5	1	13	9	6	2	14	10	7	3	15	11
$P_2(j)$	8	4	0	12	9	5	1	13	10	6	2	14	11	7	3	15
$P_3(j)$	12	8	4	0	13	9	5	1	14	10	6	2	15	11	7	3

One thing to take note of is the original permutation values only show where a given byte should land, not which byte belongs to a certain position - i.e. for P_0 , byte 1 should land in position 12, but the byte belonging to position 1 is byte 4. Because **TBL** works in the latter way, we have to do some trivial rearrangements.

Assuming the correct permutation values are put into registers V_8, V_9, V_{10}, V_{11} , this now allows us to compute the permutation layer for all 16 blocks in only eight permutation instructions.

TBL V0, V0, V8	TBL V1, V1, V9
TBL V4, V4, V8	TBL V5, V5, V9
TBL V2, V2, V10	TBL V3, V3, V11
TBL V6, V6, V10	TBL V7, V7, V11

Round key function

In contrast to packing and unpacking of data which is only done once in the beginning and end, a round key is derived for every round, so the round key derivation function needs to be as fast as possible. A simple but naive approach for one round would be to generate a single round key, copy it 15 times and pack the resulting registers similar to how we proceed with the messages. Due to the cost of packing the messages, this is prohibitively expensive. Because we know where each byte group ends up after packing, we can directly XOR the round key bits to the correct position. Extending these bits to bytes can then be done simply by repeatedly shifting and ORing the registers together.

2.2 Strategies for Camellia

Chapter 3

Implementation

We will provide and discuss implementations for the presented strategies in the C programming language. Although directly writing Assembler code could result in a small performance benefit, this generally increases the work necessary by an order of magnitude for only limited results. Instruction-level optimization and in particular register allocation is left to the compiler.

3.1 Table-based

We generate a 16 by 16 array of `uint64_t` as explained in 3. The round function then consists of extracting each nibble, looking up the corresponding table value and ORing this to the new cipher state.

Listing 3.1: Table-based round function

```
1 static const uint64_t table[16][16] = {
2     { 0x0000000000000001UL, 0x0008000000002000UL,
3       0x0000000040000000UL, 0x0008000400000000UL,
4       0x0000000040002000UL, 0x0008000400020001UL,
5       0x0000000000002000UL, 0x0008000000000001UL,
6       0x0000000000002000UL, 0x0008000400000001UL,
7       0x0008000000002000UL, 0x0000000400020001UL,
8       0x0000000040000000UL, 0x0000000000000000UL,
9       0x0008000000000000UL, 0x0008000400020000UL },
10    // ...
11    { 0x0000000010000000UL, 0x0000200000008000UL,
12      0x4000000000000000UL, 0x4000000000008000UL,
13      0x4000200000000000UL, 0x4000200010008000UL,
14      0x0000200010000000UL, 0x0000000010008000UL,
15      0x0000200000000000UL, 0x4000000010008000UL,
16      0x0000200010008000UL, 0x4000200010000000UL,
17      0x4000000010000000UL, 0x0000000000000000UL,
18      0x0000000000008000UL, 0x4000200000008000UL }
```

```

19 };
20
21 uint64_t gift_64_table_subperm(const uint64_t cipher_state)
22 {
23     uint64_t new_cipher_state = 0;
24
25     for (size_t i = 0; i < 16; i++) {
26         int nibble = (cipher_state >> (i * 4)) & 0xf;
27         new_cipher_state ^= table[i][nibble];
28     }
29
30     return new_cipher_state;
31 }

```

The round function is similar for all strategies: for each round, we extract 16 bits from the key state which are then XORed to the round key, together with the precomputed round constants and the single bit. Key state updating is done using masks and shifts only which gets optimized by the compiler through bit-field extraction instructions which can extract, shift and insert a bit field at once. Intermediate values are also optimized away.

Listing 3.2: Round key generation function

```

1 void gift_64_table_generate_round_keys(uint64_t round_keys[restrict
   ROUNDS_GIFT_64],
2                                     const uint64_t key[restrict 2])
3 {
4     uint64_t key_state[] = {key[0], key[1]};
5     for (int round = 0; round < ROUNDS_GIFT_64; round++) {
6         int v = (key_state[0] >> 0) & 0xffff;
7         int u = (key_state[0] >> 16) & 0xffff;
8
9         // add round key (RK=U||V)
10        round_keys[round] = 0UL;
11        for (size_t i = 0; i < 16; i++) {
12            int key_bit_v = (v >> i) & 0x1;
13            int key_bit_u = (u >> i) & 0x1;
14            round_keys[round] ^= (uint64_t)key_bit_v << (i * 4 + 0);
15            round_keys[round] ^= (uint64_t)key_bit_u << (i * 4 + 1);
16        }
17
18        // add single bit
19        round_keys[round] ^= 1UL << 63;
20
21        // add round constants
22        round_keys[round] ^= ((round_constant[round] >> 0) & 0x1) << 3;
23        round_keys[round] ^= ((round_constant[round] >> 1) & 0x1) << 7;
24        round_keys[round] ^= ((round_constant[round] >> 2) & 0x1) << 11;
25        round_keys[round] ^= ((round_constant[round] >> 3) & 0x1) << 15;
26        round_keys[round] ^= ((round_constant[round] >> 4) & 0x1) << 19;
27        round_keys[round] ^= ((round_constant[round] >> 5) & 0x1) << 23;
28
29        // update key state
30        int k0 = (key_state[0] >> 0) & 0xffffUL;

```

```

31         int k1 = (key_state[0] >> 16) & 0xffffUL;
32         k0 = (k0 >> 12) | ((k0 & 0xfff) << 4);
33         k1 = (k1 >> 2) | ((k1 & 0x3) << 14);
34         key_state[0] >>= 32;
35         key_state[0] |= (key_state[1] & 0xffffffffUL) << 32;
36         key_state[1] >>= 32;
37         key_state[1] |= ((uint64_t)k0 << 32) | ((uint64_t)k1 << 48);
38     }
39 }

```

While this approach does not rely on ARM-specific instructions, the next two strategies do. This is why we use NEON intrinsics.

3.2 Using **vperm**

3.2.1 NEON intrinsics

The header file `<arm_neon.h>` provides ARM-specific data and function definitions including vector data types and C functions for working with these vectors. These functions are known as NEON intrinsics and give the programmer a high-level interface to most NEON instructions. Major advantages of this approach include the ease of development as the compiler takes over register allocation and load/store operations as well as performance benefits through compiler optimizations.

Standard vector data types have the format `uintnxmt` with lane width n in bits and lane count m . Array types of the format `uintnxmxct`, $c \in \{2, 3, 4\}$ are also defined which are used in operations requiring multiple parameters like **TBL** or pairwise load/stores. Intrinsics start with **v**, optionally contain a **q** after the operation name to indicate operation on a 128-bit register, and end with the lane data format. Multiplying eight pairs of 16-bit numbers **a**, **b** for example can be done via the following:

```
uint16x8_t result = vmulq_u16(a, b);
```

In this case, the compiler allocates vector registers for **a**, **b** and **result** and assembles the intrinsic to **MUL Vr.8H, Va.8H, Vb.8H**. Necessary loads and stores for the result and parameters are also handled automatically. Of special interest to us are the following intrinsics, each existing in different variants with different lane widths and also array types:

Intrinsic		Description
uint8x16_t	vreinterpretq_u8_u64(uint64x2_t)	Explicit casting
uint64_t	vgetq_lane_u64(void)	Extract a single lane
void	vsetq_lane_u64(uint64_t)	Insert a single lane
uint64x2_t	vdupq_n_u64(uint64_t)	Initialize all lanes to same value
void	vst1q_u64(uint64_t*, uint64x2_t)	Store from register to memory
uint64x2_t	vld1q_u64(uint64_t*, uint64x2_t)	Load from memory to register
uint8x16_t	veorq_u8(uint8x16_t, uint8x16_t)	bitwise XOR
uint8x16_t	vandq_u8(uint8x16_t, uint8x16_t)	bitwise AND
uint8x16_t	vorrq_u8(uint8x16_t, uint8x16_t)	bitwise OR
uint8x16_t	vmvnq_u8(uint8x16_t)	bitwise NOT
uint8x16_t	vqtbl2q_u8(uint8x16_t, uint8x16_t)	permutation (TBL)

3.3 Bitslicing
